

# Install and configure Nagios on Ubuntu 22.04

---

Services et Administration des Réseaux

## Requirements

- A virtual machine running Ubuntu 22.04.
- Root or Sudo Access: To execute administrative tasks, you'll need either root access or a user account with sudo privileges.

## Goals

- Configure Nagios under Ubuntu 22.04

## Introduction

Simple Network Management Protocol (SNMP) is an Internet Standard protocol for collecting and organizing information about managed devices on IP networks and for modifying that information to change device behavior. Devices that typically support SNMP include cable modems, routers, switches, servers, workstations, printers, and more.

SNMP is widely used in network management for network monitoring. SNMP exposes management data in the form of variables on the managed systems organized in a management information base (MIB) which describe the system status and configuration. These variables can then be remotely queried (and, in some circumstances, manipulated) by managing applications.

Three significant versions of SNMP have been developed and deployed. SNMPv1 is the original version of the protocol. More recent versions, SNMPv2c and SNMPv3, feature improvements in performance, flexibility and security.

An SNMP-managed network consists of three key components:

- Managed devices
- Agent – software which runs on managed devices
- Network management station (NMS) – software which runs on the manager.

## Step1: Update and Upgrade

The first step is to ensure that your system is up to date. Open a terminal and run the following commands:

```
# sudo apt update && apt upgrade -y
```

## Step2: Install Prerequisites

Nagios has specific software prerequisites that need to be installed on your Ubuntu 22.04 machine before you can install and configure Nagios itself. By installing all these prerequisites, you ensure that your Ubuntu 22.04 system has all the necessary dependencies to run Nagios optimally and enable efficient monitoring of your systems and services.

```
# sudo apt install build-essential apache2 php libgd-dev libapache2-mod-php libperl-dev libssl-dev daemon wget
```

## Step 3: Create a Nagios User and Group

Nagios should run as a separate user and group. Create them with the following commands:

```
# sudo useradd nagios
# sudo groupadd nagcmd
# sudo usermod -a -G nagcmd nagios
# sudo usermod -a -G nagios,nagcmd www-data
```

## Step 4: Download Nagios on Ubuntu

We are performing a manual installation. To do so, download the tar.gz file via the following command.

```
# cd ~
# wget https://github.com/NagiosEnterprises/nagioscore/releases/download/nagios-4.4.6/nagios-4.4.6.tar.gz
```

## Step 5: Extract downloaded tar.gz file

Once you have downloaded the Nagios source code, you can extract its contents and proceed with the compilation and installation.

The file is available as “nagios-4.4.6.tar.gz“. We executed the following command to extract it.

```
# tar -xzf nagios-4.4.6.tar.gz
```

## Step6: Compile Nagios Core

Make sure, you are inside the directory where the Nagios is extracted. Next, configure Nagios on Ubuntu and compile it:

```
# cd nagios-4.4.6

# sudo ./configure --with-nagios-group=nagios --with-command-group=nagcmd

# sudo make all
```

## Step7: Install Nagios Core Binaries and Web Interface Files

```
# sudo make install

# sudo make install-commandmode

# sudo make install-init

# sudo make install-config

# sudo /usr/bin/install -c -m 644 sample-config/httpd.conf /etc/apache2/sites-available/nagios.conf

# sudo cp -R contrib/eventhandlers/ /usr/local/nagios/libexec/

# sudo chown -R nagios:nagios /usr/local/nagios/libexec/eventhandlers
```

## Step8: Download, Extract and Install Nagios on Ubuntu Plugins

```
# wget https://nagios-plugins.org/download/nagios-plugins-2.1.2.tar.gz

# tar -xzf nagios-plugins*.tar.gz

# cd nagios-plugins-2.1.2/

# ./configure --with-nagios-user=nagios --with-nagios-group=nagios --with-openssl

# sudo make

# sudo make install
```

## Step9: Configuring Nagios

1- uncomment line 51 for the host monitor configuration. `cfg_dir=/usr/local/nagios/etc/servers`

Save and exit.

```
# sudo gedit /usr/local/nagios/etc/nagios.cfg
```

2- Add a new folder named servers:

```
# sudo mkdir -p /usr/local/nagios/etc/servers
```

3- The Nagios contact can be configured in the `contact.cfg` file. To open it use:

```
# sudo gedit /usr/local/nagios/etc/objects/contacts.cfg
```

Then replace the default email with your own email.

## Step 10: Configuring apache2

1- Enable the Nagios virtualhost

```
# sudo ln -s /etc/apache2/sites-available/nagios.conf /etc/apache2/sites-enabled/
```

2- Nagios utilizes the Apache web server as part of its setup for hosting its web interface. To make sure everything works properly, you need to enable specific Apache modules and then restart the Apache service.

```
# sudo a2enmod rewrite cgi
```

```
# sudo systemctl restart apache2
```

➤ The `a2enmod` command enables the required Apache modules for Nagios.

## Step 11: Set Nagios Admin Password

You will be prompted to set a password for the user 'nagiosadmin.' Please make note of this password as it will be used to access the Nagios web interface.

```
# sudo htpasswd -c /usr/local/nagios/etc/htpasswd.users nagiosadmin
```

## Step 12: Start Nagios and Apache Services

By executing these commands, you'll have both Nagios and Apache running on your Ubuntu system, allowing you to access the Nagios web interface and start monitoring your infrastructure.

```
# sudo systemctl enable nagios  
  
# sudo systemctl enable apache2  
  
# sudo systemctl restart nagios  
  
# sudo systemctl restart apache2
```

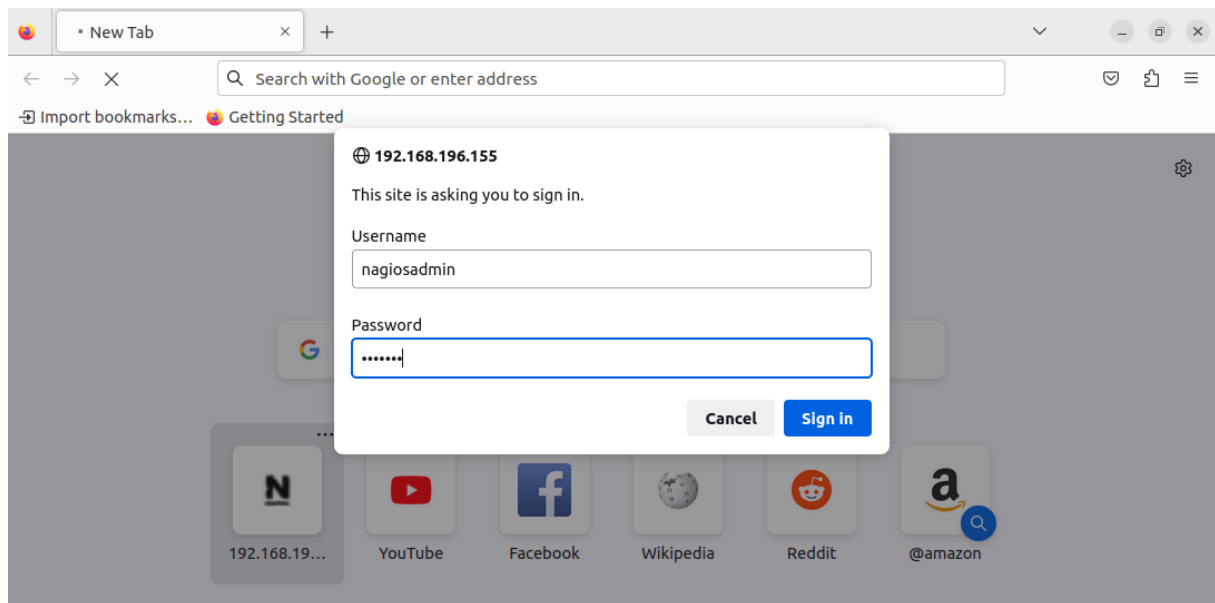

## Step 13: Access Nagios Web Dashboard

In the address bar of the web browser, enter the IP address or hostname of your Ubuntu server, followed by “/nagios”.

```
http://your_server_ip_or_hostname/nagios
```

Replace “your\_server\_ip” with the actual IP address or hostname of your Ubuntu server where Nagios is installed

Log in to the web interface with the username nagiosadmin and the password you set during installation. (By default, the username is “nagiosadmin.”)

In the above screenshot, you will only see the localhost. To monitor remote machines, you will need to add the host to Nagios.

Host	Status	Last Check	Duration	Status Information
localhost	UP	10-08-2023 00:44:36	0d 1h 51m 41s	PING OK - Packet loss = 0%, RTA = 0.05 ms

## Step 14: Adding the host to Nagios

Open a terminal and navigate to the directory where Nagios configurations are stored. The default path is `/usr/local/nagios/etc/servers`

You should already have a `host.cfg` file or create one if it doesn't exist.

In the host.cfg file, you need to define the host you want to monitor. Here's an example configuration:

```
Open  host.cfg
/usr/local/nagios/etc/servers

1 define host {
2     use                               linux-server
3     host_name                         machine-physique
4     alias                             machine physique
5     address                           192.168.1.30
6     max_check_attempts                3
7     check_period                      24x7
8     notification_interval              30
9     notification_period                24x7
10
11 }
12
13 define host {
14     use                               linux-server
15     host_name                         web-server-vm
16     alias                             serveur web déployé sur une 2ème vm
17     address                           192.168.196.153
18     max_check_attempts                3
19     check_period                      24x7
20     notification_interval              30
21     notification_period                24x7
22
23 }
```

```
define host {
    use                               linux-server
    host_name                         machine-physique
    alias                             machine physique
    address                           192.168.1.30
    max_check_attempts                3
    check_period                      24x7
    notification_interval              30
    notification_period                24x7
}
```

```
# sudo systemctl restart apache2
# sudo systemctl reload nagios
```

Click on hosts in the left pane to see hosts being monitored by Nagios.

The screenshot shows the Nagios web interface. The left sidebar contains navigation links: General (Home, Documentation), Current Status (Tactical Overview, Map (Legacy), Hosts, Services, Host Groups, Service Groups, Problems), and a Quick Search bar. The main content area displays the 'Host Status Details For All Host Groups'. At the top, there are summary boxes for 'Current Network Status', 'Host Status Totals' (Up: 3, Down: 0, Unreachable: 0, Pending: 0), and 'Service Status Totals' (Ok: 7, Warning: 0, Unknown: 0, Critical: 1, Pending: 0). Below these, a table lists the monitored hosts:

Host	Status	Last Check	Duration	Status Information
localhost	UP	10-08-2023 13:47:34	0d 0h 59m 38s	PING OK - Packet loss = 0%, RTA = 0.10 ms
machine-physique	UP	10-08-2023 13:46:23	0d 0h 8m 58s	PING OK - Packet loss = 0%, RTA = 1.25 ms
web-server-vm	UP	10-08-2023 13:50:07	0d 0h 0m 14s	PING OK - Packet loss = 0%, RTA = 0.94 ms

Below the table, it indicates 'Results 1 - 3 of 3 Matching Hosts'.

Here's an example configuration of a PING service in Nagios:
